OPINION

Evolution of strategies to improve preclinical cardiac safety testing

Gary Gintant, Philip T. Sager and Norman Stockbridge

Abstract | The early and efficient assessment of cardiac safety liabilities is essential to confidently advance novel drug candidates. This article discusses evolving mechanistically based preclinical strategies for detecting drug-induced electrophysiological and structural cardiotoxicity using *in vitro* human ion channel assays, human-based *in silico* reconstructions and human stem cell-derived cardiomyocytes. These strategies represent a paradigm shift from current approaches, which rely on simplistic *in vitro* assays that measure blockade of the K_v11.1 current (also known as the hERG current or I_{Kr}) and on the use of non-human cells or tissues. These new strategies have the potential to improve sensitivity and specificity in the early detection of genuine cardiotoxicity risks, thereby reducing the likelihood of mistakenly discarding viable drug candidates and speeding the progression of worthy drugs into clinical trials.

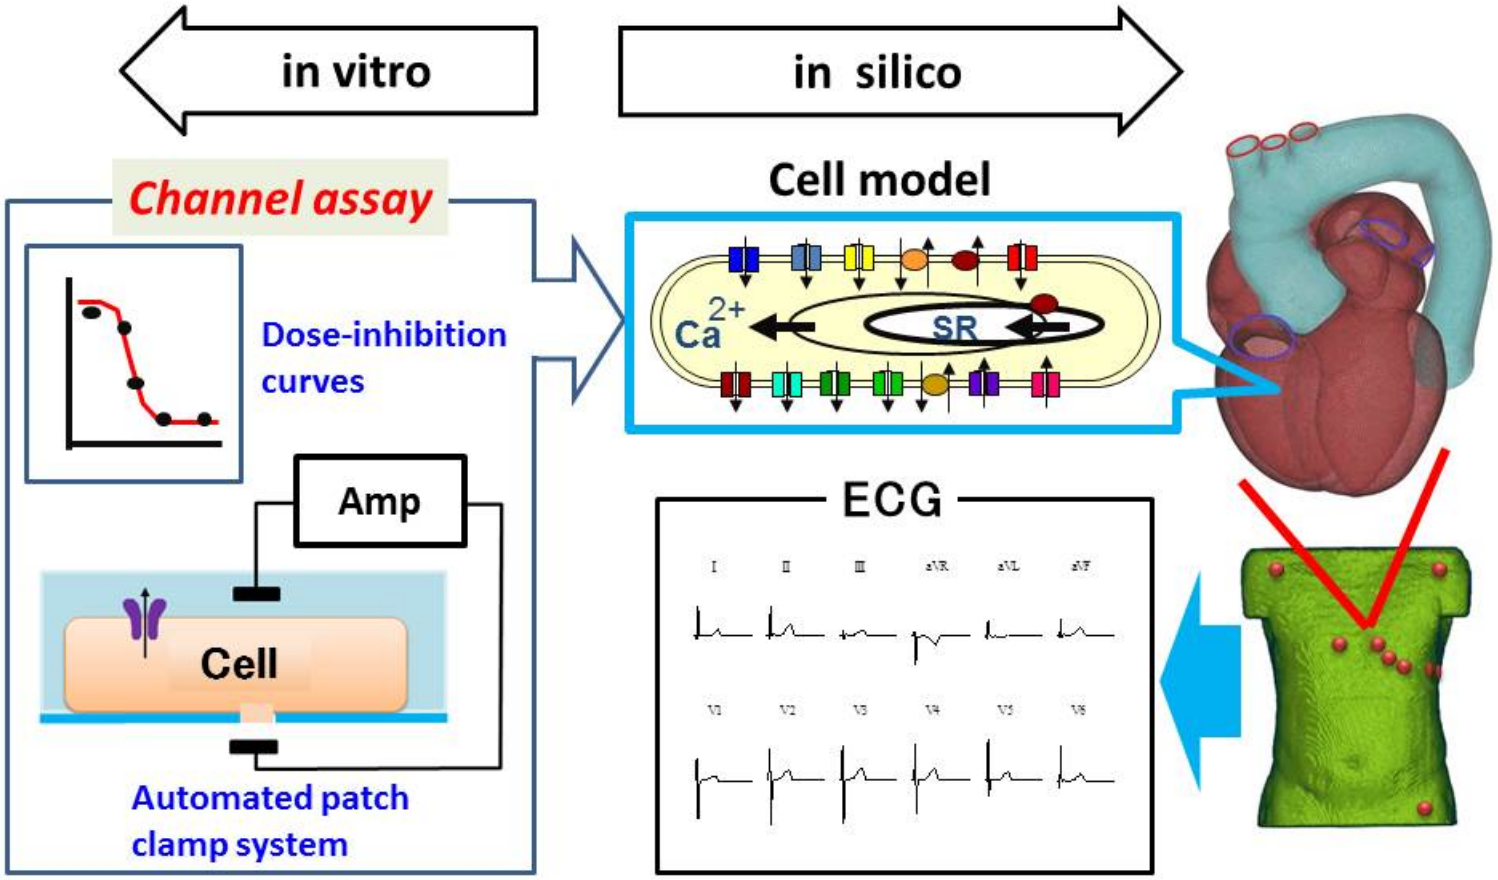
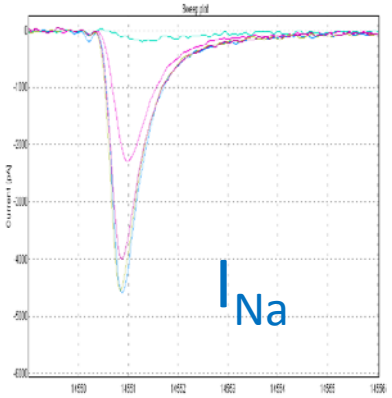
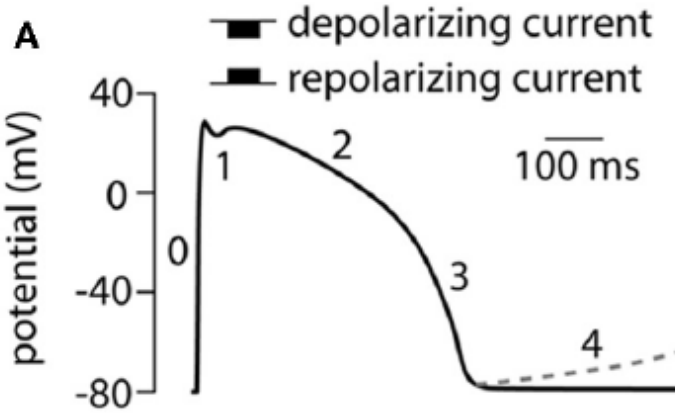
Diagram of the Arrhythmia Prediction system

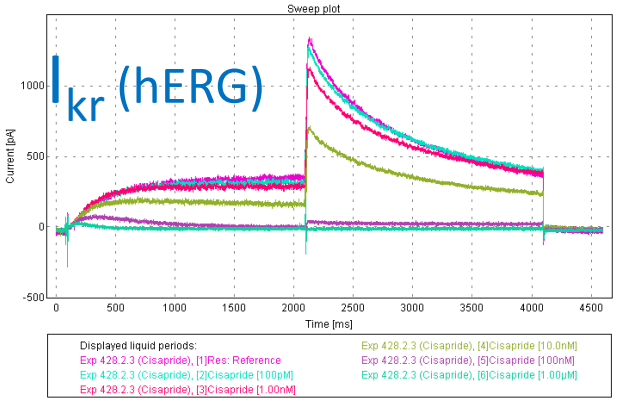


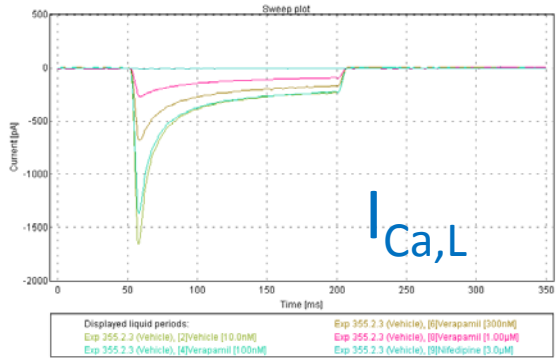
- Concentration-inhibition curves of drugs were obtained using the automated patch clamp system (QPatch-HTX).
- The 12-lead ECG waveform were calculated by high performance computer.
- The effects of drugs on ECG waveforms were simulated based on the ion channel inhibition data.

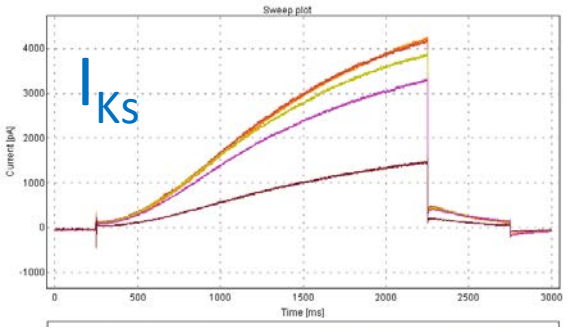
Multi-ion channel data is essential for QT and arrhythmia risk prediction

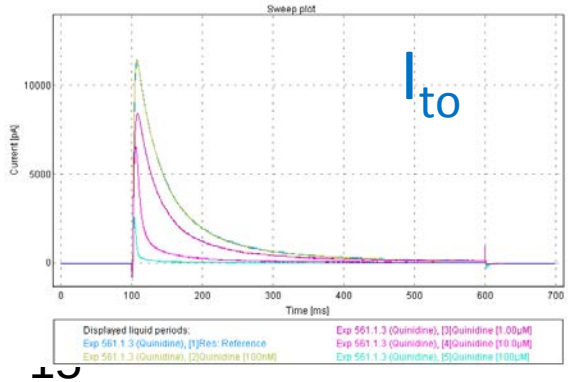


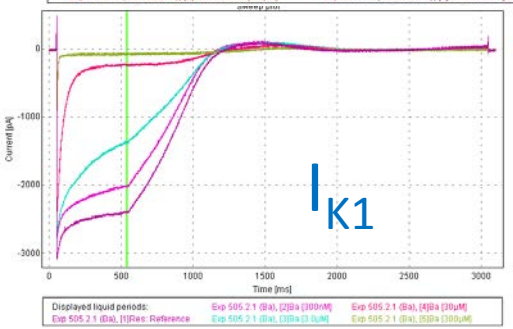




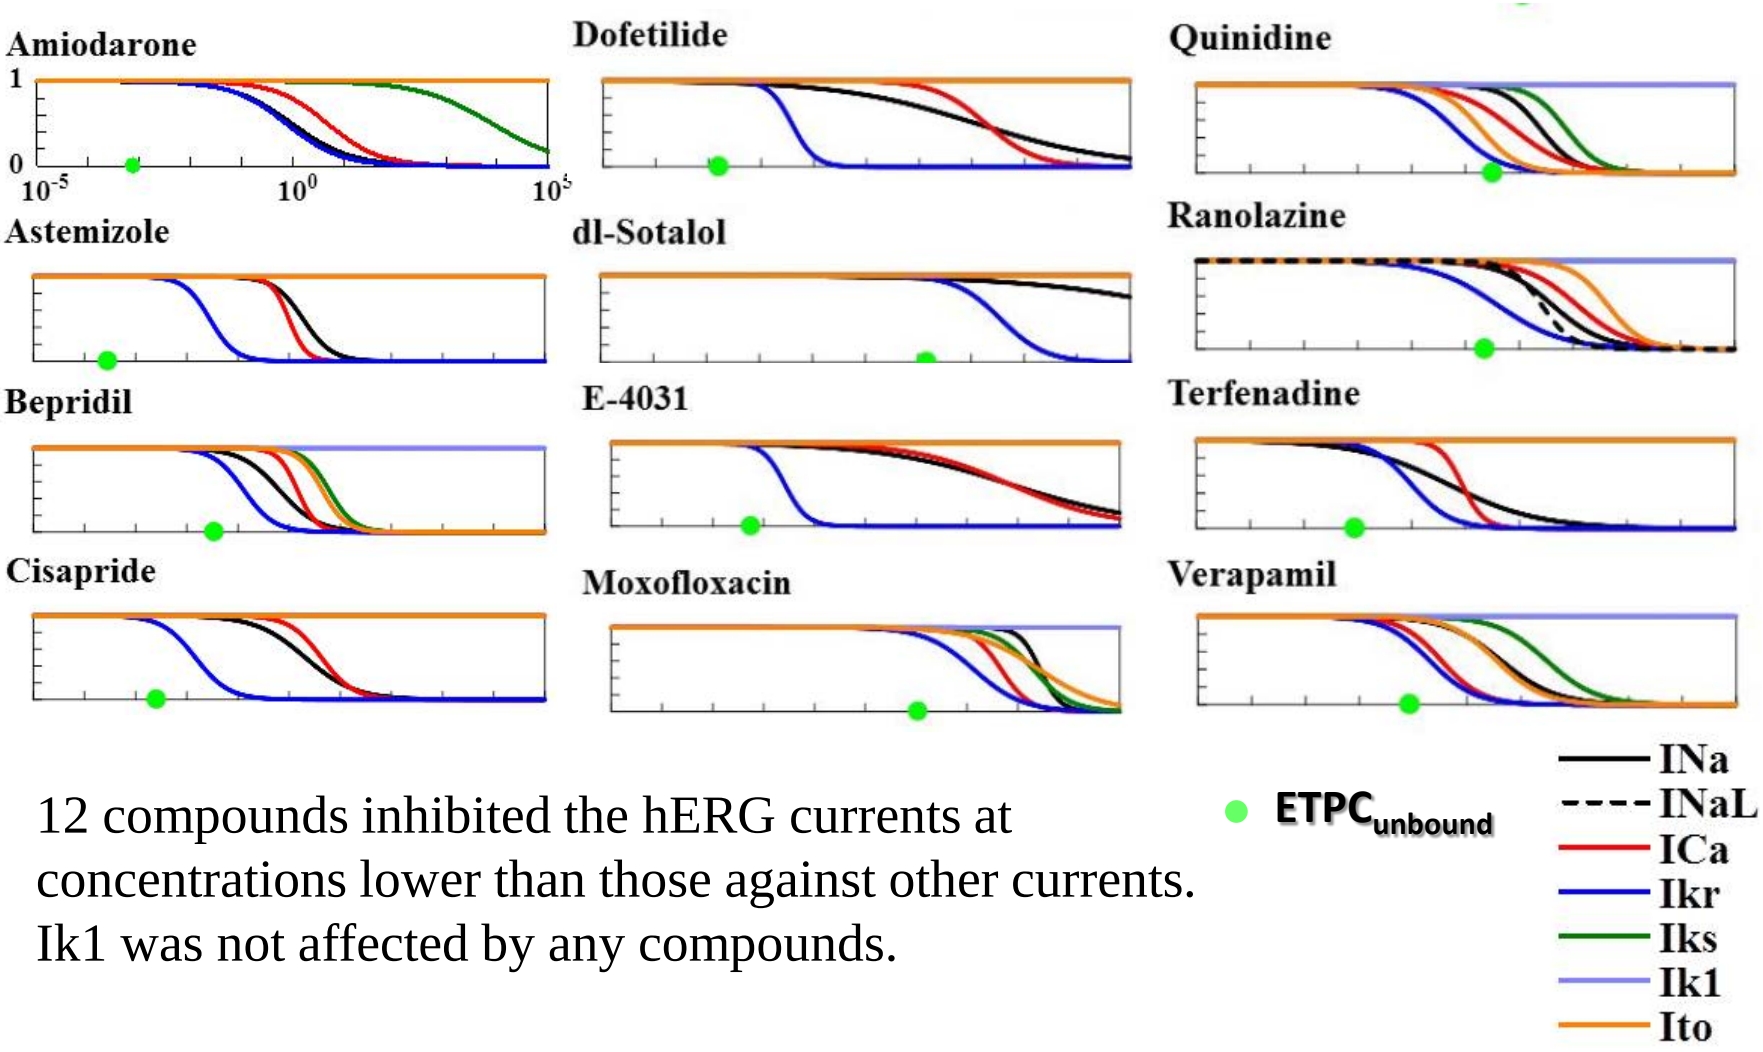








Concentration-inhibition curves for six ion channels



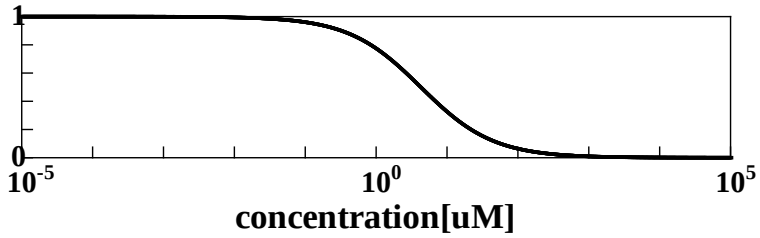
12 compounds inhibited the hERG currents at concentrations lower than those against other currents. Ik1 was not affected by any compounds.

J. Okada *et al.*, *Science Advances Vol.1 no.4 e1400142(2015)*

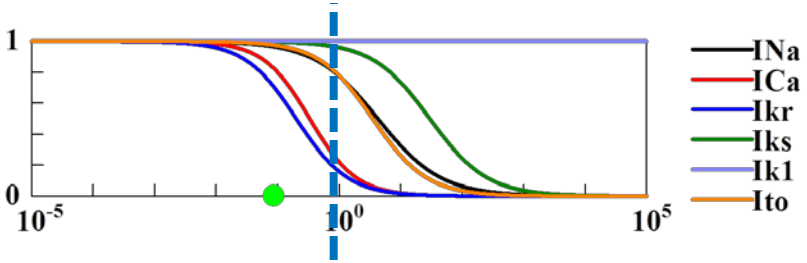
Concentration-inhibition curves for six ion channels

- Ion channels: hERG (I_{Kr}), Nav1.5, (I_{Na}), Cav1.2/β2/α2-δ (I_{Ca}), KCNQ1+KCNE1 (I_{Ks}), Kir2.1 (I_{K1}) or Kv4.3+KChiIP2 (I_{to}) channels
- Methods: automated patch clamp systems(the Sophion QPatch HTX system), general voltage protocols, room temperature
- Calculated parameters, IC_{50}, Hill coefficient, relative current

$$\text{Relative current} = \frac{1}{1 + 10^{(logIC_{50} - logx)\cdot n_H}}$$



- Example of Drug Effect Modeling

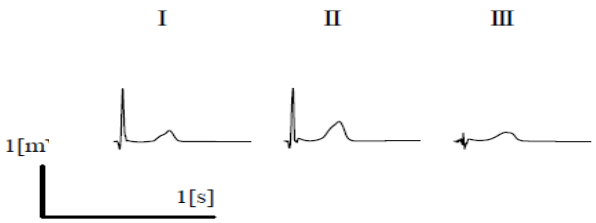


INa* = INa × 0.793039
ICaL* = ICaL × 0.246904
ICaK* = ICaK × 0.246904
ICaNa* = ICaNa × 0.246904
IKr* = IKr × 0.177410
IKs* = IKs × 0.96401
IK1* = IK1 × 1.000000
Ito* = Ito × 0.798373

E-4031 induced TdP

Simulated ECG

Basal condition



Clinical case of TdP with E4031: 9mg/man, day 6

3D Hazard map for arrhythmia

Unpublished

Summary and Conclusions

The development and improvement of *in silico* simulation for the cardiac electrophysiology such as ventricular action potentials and ECGs are progressed in the safety pharmacology field.

Using *in vitro* (multi-ion channel inhibition) data, UT-heart could predict the drug-induced arrhythmogenic risk potential of TdP-negative or –positive drugs.

Applying this technology, the hazard map for arrhythmia using ECG database based on the various combinations of multi-ion channel inhibition data has been developed.
